# EE2S11 Signals and Systems <br> Chapter 11: The Discrete-Time Fourier Transform (DTFT) 

Alle-Jan van der Veen

10 January 2024

## Contents

- definition of the DTFT
- relation to the $z$-transform, region of convergence, stability
- frequency plots
- inverse DTFT
- extensions
- shifts and modulations

Skip sections 11.2.4.1 (decimation/interpolation), 11.3 (Fourier Series), 11.4 (DFT). These are covered in EE2S31.

## The Discrete-time Fourier transform (DTFT)

The DTFT is defined as

$$
X(\omega)=\mathcal{F}\{x[n]\}:=\sum_{n=-\infty}^{\infty} x[n] e^{-j \omega n}
$$

- Continuous function of $\omega$ (while $x[n]$ is a time series)
- $X(\omega+2 \pi)=X(\omega)$ : periodic in $\omega$, period $2 \pi$ : It sufficies to consider the interval $\omega \in[-\pi, \pi]$.
- $X(\omega)$ is called "the spectrum"; it measures the frequency content
- Sufficient condition for convergence of the infinite sum:

$$
\left|\sum_{n=-\infty}^{\infty} x[n] e^{-j \omega n}\right| \leq \sum_{n=-\infty}^{\infty}|x[n]|\left|e^{-j \omega n}\right|=\sum_{n=-\infty}^{\infty}|x[n]|<\infty
$$

i.e., $x[n]$ is absolutely summable $\left(x \in \ell_{1}\right)$.

## Relation to the z-transform

The DTFT is obtained from the $z$-transform by setting $z=e^{j \omega}$ (assuming that the unit circle $|z|=1$ is in de ROC).
We often write $X(\omega)$ as $X\left(e^{j \omega}\right)$, cf. the book. (The book's notation avoids confusion between $X(\omega)$ and $X(z)$, different functions.)

We immediately obtain (LTI systems):

- $y[n]=h[n] * x[n]$
$\Leftrightarrow$

$$
Y(\omega)=H(\omega) X(\omega)
$$

(filters!)
■ $H(\omega)=\sum h[n] e^{-j \omega n}$ exists if the system is BIBO stable $\left(h \in \ell_{1}\right.$, ie., the unit circle is in the ROC of $H(z)$ ).

- $\delta[n]$
$\Leftrightarrow \quad 1$
$u[n]$
$\Leftrightarrow \quad$ (no ordinary DTFT because of ROC)
$\delta[n-N]$
$a^{n} u[n] \quad(|a|<1)$
$\Leftrightarrow \quad \frac{1}{1-a e^{-j \omega}}$

## Exercise [trial exam 2016]

Given $X(\omega)=\cos (\omega)$, determine $x[n]$.

## Exercise [trial exam 2016]

Given $X(\omega)=\cos (\omega)$, determine $x[n]$.

$$
X(\omega)=\frac{1}{2} e^{j \omega}+\frac{1}{2} e^{-j \omega} \Rightarrow x[n]=\frac{1}{2} \delta[n+1]+\frac{1}{2} \delta[n-1]
$$

## Exercise [exam January 2023]

Given the DTFT $X\left(e^{j \omega}\right)=e^{-j 2 \omega} \cos ^{2}(\omega)$. Determine $x[n]$.
Hint: first determine the $z$-transform.

## Exercise [exam January 2023]

Given the DTFT $X\left(e^{j \omega}\right)=e^{-j 2 \omega} \cos ^{2}(\omega)$. Determine $x[n]$.
Hint: first determine the $z$-transform.

Rewrite (using $z=e^{j \omega}$ ) as a function of $z$ :

$$
X(z)=z^{-2} \frac{1}{4}\left(z+z^{-1}\right)^{2}=\frac{1}{4}\left(1+2 z^{-2}+z^{-4}\right)
$$

Hence

$$
x[n]=\frac{1}{4}(\delta[n]+2 \delta[n-2]+\delta[n-4])
$$

## Frequency plots

$X(\omega)$ is complex. To make a plot, write $X(\omega)=|X(\omega)| e^{j \phi(\omega)}$, where $|X(\omega)|$ : amplitude spectrum, $\phi(\omega)$ : phase spectrum

## Example

plot the amplitude and phase spectrum of $X(\omega)=\frac{1}{1-a e^{-j \omega}}$

- Amplitude spectrum $|X(\omega)|$ is found via

$$
|X(\omega)|^{2}=X(\omega) X^{*}(\omega)=\frac{1}{1-a e^{-j \omega}} \frac{1}{1-a e^{j \omega}}=\frac{1}{1+a^{2}-2 a \cos (\omega)}
$$

- Phase spectrum

$$
\begin{aligned}
& \frac{1}{1-a e^{-j \omega}}=\frac{1}{(1-a \cos (\omega))+j a \sin (\omega)} \\
\Rightarrow \quad & \phi(\omega)=-\tan ^{-1}\left(\frac{a \sin (\omega)}{1-a \cos (\omega)}\right)
\end{aligned}
$$

## Discrete-time Fourier Transform

$\phi(\omega)$

$\phi(\omega)$

## Estimating frequency plots using phasors

Given a rational transfer function, e.g. $X(z)=\frac{z-b}{z-a}$, we can sketch a plot of $|X(\omega)|$ and $\phi(\omega)$ using phasors.

$$
\begin{aligned}
& |X(\omega)|=\frac{|z-b|}{|z-a|} \\
& \phi(\omega)= \\
& \angle(z-b)-\angle(z-a) \bmod 2 \pi
\end{aligned}
$$

## Estimating frequency plots using phasors

To gain some insight: compute this for a number of values of $\omega$.

$\phi(\omega)$

$\phi(\omega)$

## Exercise [exam January 2021]

Sketch the magnitude spectrum $\left|H\left(e^{j \omega}\right)\right|$ corresponding to the pole-zero plot:

## Exercise [exam January 2021]

Sketch the magnitude spectrum $\left|H\left(e^{j \omega}\right)\right|$ corresponding to the pole-zero plot:

## Example: DTFT of a pulse

$p[n]=u[n]-u[n-N]$,
pulse of length $N$

$$
j_{h} z \text {-plane }
$$

$$
P(z)=1+z^{-1}+\cdots+z^{-(N-1)}=\frac{1-z^{-N}}{1-z^{-1}}
$$

$$
\begin{aligned}
P(\omega) & =\frac{1-e^{-j \omega N}}{1-e^{-j \omega}}=\frac{e^{j \omega N / 2}-e^{-j \omega N / 2}}{e^{j \omega / 2}-e^{-j \omega / 2}} e^{-j \omega(N-1) / 2} \\
& =\frac{\sin (\omega N / 2)}{\sin (\omega / 2)} e^{-j \omega(N-1) / 2}
\end{aligned}
$$

## DTFT of a pulse (cont'd)

- The amplitude spectrum is

$$
A(\omega)=|P(\omega)|=\left|\frac{\sin (\omega N / 2)}{\sin (\omega / 2)}\right|
$$

"periodic sinc-function" (Dirichlet-function) with $A(0)=N$

- The phase spectrum is $\phi(\omega)=-\omega(N-1) / 2$ (lineair phase) plus phase jumps of $\pi$ due to sign changes of $\sin (\omega N / 2)$.

$\phi(\omega)$

$(N=8)$
zero crossings for $\omega= \pm \frac{2 \pi}{N} k(k \neq 0)$
Phase slope $\Leftrightarrow$ delay
Phase jumps $(\pi) \Leftrightarrow$ change of sign

## DTFT of a pulse (cont'd)

- The linear phase corresponds to a delay $z^{-(N-1) / 2}$, half the duration of the pulse.
- The first zero in the amplitude spectrum (right of the peak at $\omega=0$ ) gives an indication of the "bandwidth"

$$
\Delta \omega=\frac{2 \pi}{N}
$$

The "bandwidth" is inversely proportional to the duration of the pulse.
In many applications where we collect $N$ samples (or have $N$ uniformly spaced sensors), this is related to the resolution of a system.

Example: DTFT of a non-causal signal
Determine the spectrum of the non-causal signal $x[n]=a^{|n|}$ with $|a|<1$.

## Example: DTFT of a non-causal signal

Determine the spectrum of the non-causal signal $x[n]=a^{|n|}$ with $|a|<1$.

The $z$-transform of $x[n]$ is

$$
X(z)=\sum_{n=0}^{\infty} a^{n} z^{-n}+\sum_{n=0}^{\infty} a^{n} z^{n}-1=\frac{1}{1-a z^{-1}}+\frac{1}{1-a z}-1=\frac{1-a^{2}}{1-a\left(z+z^{-1}\right)+a^{2}}
$$

with as ROC the intersection of the ROC of the causal and anti-causal part:

$$
\mathrm{ROC}:|a|<|z|<\frac{1}{|a|}
$$

The ROC contains the unit circle. Hence

$$
X(\omega)=X\left(z=e^{j \omega}\right)=\frac{1-a^{2}}{1-a\left(e^{j \omega}+e^{-j \omega}\right)+a^{2}}=\frac{1-a^{2}}{1+a^{2}-2 a \cos (\omega)}
$$

Note that $x[n]$ is even and $X(\omega)$ is real-valued $(\phi(\omega)=0)$.

## Relation to the continuous-time Fourier Transform

Consider a signal $x(t)$ and sample it with period $T_{s}$,

$$
x_{s}(t)=\sum_{n} x\left(n T_{s}\right) \delta\left(t-n T_{s}\right)
$$

The (continous-time) Fourier transform is

$$
X_{s}(\Omega)=\mathcal{F}\left\{x_{s}(t)\right\}=\sum_{n} x\left(n T_{s}\right) \mathcal{F}\left\{\delta\left(t-n T_{s}\right)\right\}=\sum x\left(n T_{s}\right) e^{-j n \Omega T_{s}}
$$

Set $\omega=\Omega T_{s}$ and $x[n]=x\left(n T_{s}\right)$. Then

$$
X_{s}(\Omega)=\mathcal{F}\left\{x_{s}(t)\right\}=\sum_{n} x[n] e^{-j n \omega}=: X(\omega)
$$

The definition of $X(\omega)$ (spectrum of a time series) is consistent to that of $X_{s}(\Omega)$ (spectrum of a continuous-time signal).

## Inverse DTFT

$$
x[n]=\frac{1}{2 \pi} \int_{-\pi}^{\pi} X(\omega) e^{j \omega n} \mathrm{~d} \omega=\int_{-1 / 2}^{1 / 2} X(f) e^{j 2 \pi f n} \mathrm{~d} f \quad(\text { with } \omega=2 \pi f)
$$

The integral runs over 1 period of the spectrum.
Proof

$$
\begin{aligned}
\frac{1}{2 \pi} \int_{-\pi}^{\pi} X(\omega) e^{j \omega n} d \omega & =\frac{1}{2 \pi} \int_{-\pi}^{\pi}\left[\sum_{k=-\infty}^{\infty} x[k] e^{-j \omega k}\right] e^{j \omega n} d \omega \\
& =\frac{1}{2 \pi} \sum_{k=-\infty}^{\infty} x[k]\left[\int_{-\pi}^{\pi} e^{j \omega(n-k)} d \omega\right] \\
& =\frac{1}{2 \pi} \sum_{k=-\infty}^{\infty} x[k] \cdot 2 \pi \delta[n-k]=x[n]
\end{aligned}
$$

## Energy (Parseval)

$$
E_{x}=\sum_{n=-\infty}^{\infty}|x[n]|^{2}=\frac{1}{2 \pi} \int_{-\pi}^{\pi}|X(\omega)|^{2} \mathrm{~d} \omega
$$

$S_{x}(\omega):=|X(\omega)|^{2}$ is called the energy spectrum ("energy spectral density": energy per radial)

## Proof

$$
\begin{aligned}
E_{X} & =\sum_{n}|x[n]|^{2}=\sum_{n} x[n] x^{*}[n] \\
& =\sum_{n} x[n]\left[\frac{1}{2 \pi} \int_{-\pi}^{\pi} X^{*}(\omega) e^{-j \omega n} \mathrm{~d} \omega\right] \\
& =\frac{1}{2 \pi} \int_{-\pi}^{\pi} X^{*}(\omega)\left[\sum_{n} x[n] e^{-j \omega n}\right] \mathrm{d} \omega \\
& =\frac{1}{2 \pi} \int_{-\pi}^{\pi}|X(\omega)|^{2} \mathrm{~d} \omega
\end{aligned}
$$

## Extensions

A sufficient condition for the existence of the DTFT was that the signal is absolutely summable. But also for some other signals we can define the DTFT.

## Extension to signals with finite energy

Signals with finite energy ( $x \in \ell_{2}$ ) are not always absolutely summable (the reverse does hold: $\ell_{1} \subset \ell_{2}$ ). Due to Parseval, the spectrum has equal energy: also finite. We can define a DTFT pair (signal/spectrum) based on the Inverse DTFT (integral over a finite interval).

## Example

Ideal low-pass filter:

$$
G(\omega)=\left\{\begin{array}{ll}
1, & -\omega_{0} \leq \omega \leq \omega_{0}, \\
0, & \text { elsewhere }
\end{array} \quad \text { with copies every } 2 \pi k\right.
$$

## Ideal low-pass filter

$$
\begin{aligned}
g[n] & =\frac{1}{2 \pi} \int_{-\pi}^{\pi} G(\omega) e^{j \omega n} d \omega=\frac{1}{2 \pi} \int_{-\omega_{0}}^{\omega_{0}} e^{j \omega n} d \omega=\frac{1}{2 \pi}\left[\frac{e^{j \omega n}}{j n}\right]_{-\omega_{0}}^{\omega_{0}} \\
& =\frac{\sin \left(\omega_{0} n\right)}{\pi n}
\end{aligned}
$$

$g[n]$ has finite energy but is not absolutely summable (because $\frac{1}{n}$ converges to 0 very slowly)

## Further extension to non-absolutely summable signals

 According to the equation, the Inverse DTFT of $2 \pi \delta\left(\omega-\omega_{0}\right)$ equals$$
\frac{1}{2 \pi} \int_{-\pi}^{\pi} 2 \pi \delta\left(\omega-\omega_{0}\right) e^{j \omega n} d \omega=e^{j \omega_{0} n}
$$

Hence

$$
e^{j \omega_{0} n} \quad \Leftrightarrow \quad 2 \pi \delta\left(\omega-\omega_{0}\right)
$$

This can be used to compute the DTFT of some signals which are not absolutely summable nor have finite energy (with impulses in the frequency domain), e.g., periodic signals.

■ $x[n]=A \quad(-\infty<n<\infty)$ (constant signal) is not absolutely summable. The DTFT is

$$
X(\omega)=2 \pi A \delta(\omega), \quad-\pi \leq \omega<\pi
$$

Outside this interval: periodic (period $2 \pi$ ), or

$$
X(\omega)=2 \pi A \sum_{k} \delta(\omega-2 \pi k) .
$$

## Cosine signals

The DTFT of $x[n]=\cos \left(\omega_{0} n+\theta\right)=\frac{1}{2}\left[e^{j\left(\omega_{0} n+\theta\right)}+e^{-j\left(\omega_{0} n+\theta\right)}\right]$ is

$$
X(\omega)=\pi\left[e^{j \theta} \delta\left(\omega-\omega_{0}\right)+e^{-j \theta} \delta\left(\omega+\omega_{0}\right)\right], \quad-\pi \leq \omega<\pi
$$

Outside this interval: periodic (period $2 \pi$ ).

## Periodic signals

More in general, consider

$$
\begin{array}{rlrl}
x[n] & =\sum_{\ell} A_{\ell} \cos \left(\omega_{\ell} n+\theta_{\ell}\right) \\
\Leftrightarrow & X(\omega) & =\sum_{\ell} \pi A_{\ell}\left[e^{j \theta_{\ell}} \delta\left(\omega-\omega_{\ell}\right)+e^{-j \theta_{\ell}} \delta\left(\omega+\omega_{\ell}\right)\right]
\end{array}
$$

for $-\pi \leq \omega<\pi$ (periodic outside this interval).

A periodic signal $x[n]$ has harmonically related frequencies: $\omega_{\ell}=\ell \omega_{0}$, with $\omega_{0}=\frac{2 \pi}{N}$, where $N$ is the period (in samples). We obtain a line spectrum, just like with the Fourier Series.

## Unit step

The $z$-transform of a unit step $u[n]$ is

$$
\frac{1}{1-z^{-1}}, \quad \operatorname{ROC}:|z|>1
$$

The unit cicle is not in the ROC, thus the DTFT can only be defined in generalized sense. ( $u[n]$ is not absolutely summable and does not have finite energy.)
Define the discrete-time "sign" function:

$$
\operatorname{sgn}[n]= \begin{cases}1, & n \geq 0 \\ -1, & n<0\end{cases}
$$

Then

$$
\begin{array}{rll}
\operatorname{sgn}[n] & \Leftrightarrow & \frac{2}{1-e^{-j \omega}} \\
u[n]=\frac{1}{2}+\frac{1}{2} \operatorname{sgn}[n] & \Leftrightarrow & \pi \sum_{k} \delta(\omega-2 \pi k)+\frac{1}{1-e^{-j \omega}}
\end{array}
$$

## Unit step (cont'd)

## Proof (indication)

Using the Fourier transform of

$$
\delta[n]=u[n]-u[n-1]=\frac{1}{2}(\operatorname{sgn}[n]-\operatorname{sgn}[n-1]):
$$

$$
\begin{aligned}
& 1=\frac{1}{2} \mathcal{F}\{\operatorname{sgn}[n]\}-\frac{1}{2} \mathcal{F}\{\operatorname{sgn}[n-1]\}=\frac{1}{2} \mathcal{F}\{\operatorname{sgn}[n]\}-\frac{1}{2} e^{-j \omega} \mathcal{F}\{\operatorname{sgn}[n]\} \\
\Rightarrow & \mathcal{F}\{\operatorname{sgn}[n]\}=\frac{2}{1-e^{-j \omega}} \quad \text { for } \omega \neq \cdots, 0,2 \pi, 4 \pi, \cdots
\end{aligned}
$$

For $\omega=\cdots, 0,2 \pi, 4 \pi, \cdots$ we consider the DC component of the function, which equals 0 (in contrast to $u[n]$, which motivates why we looked at sng[n]).
$\mathcal{F}\{u[n]\}$ has impulses at these frequencies.
Compare this to the Fourier transform of a continuous-time step function:

$$
\mathcal{F}\{u(t)\}=\frac{1}{j \Omega}+\pi \delta(\Omega) .
$$

## Shift in time

If $y[n]=x[n-N]$ is a delay by $N$ samples, then

$$
Y(\omega)=\sum_{n} x[n-N] e^{-j \omega n}=e^{-j \omega N} X(\omega)
$$

- The delay only affects the phase, which drops by $-\omega N$.
- Generally, a filter $H(\omega)$ that shows a linear phase term $(-\omega N)$ inserts a delay of $N$ samples.
This is called the phase delay: the delay that a sinusoid of frequency $\omega$ would experience.
Also used is group delay: the derivative (slope) of the phase response.

## Shift in frequency

If

$$
Y(\omega)=X\left(\omega-\omega_{0}\right)
$$

is a frequency shift of $X(\omega)$ by $\omega_{0}$, then

$$
y[n]=x[n] \cdot e^{j \omega_{0} n}
$$

$y[n]$ equals $x[n]$ modulated by a complex exponential function $\mathrm{e}^{\mathrm{j} \omega_{0} n}$.

- Likewise:

$$
\begin{array}{lll}
x[n] \cdot \cos \left(\omega_{0} n\right) & \Leftrightarrow & \frac{1}{2}\left[X\left(\omega-\omega_{0}\right)+X\left(\omega+\omega_{0}\right)\right] \\
x[n] \cdot \sin \left(\omega_{0} n\right) & \Leftrightarrow & -\frac{j}{2}\left[X\left(\omega-\omega_{0}\right)-X\left(\omega+\omega_{0}\right)\right]
\end{array}
$$

The modulation shifts the spectrum of $x[n]$ to frequency $\omega_{0}$.

## Example of modulation

$$
x[n]=a^{|n|} \cos \left(\omega_{0} n\right) \quad \text { with } a=0.95, \omega_{0}=\frac{2 \pi}{10}
$$

## More generally: product of two signals

The DTFT of the product $x[n] y[n]$ is

$$
\begin{aligned}
\sum x[n] y[n] e^{-j \omega n} & =\sum\left[\frac{1}{2 \pi} \int X(\theta) e^{j \theta n} \mathrm{~d} \theta\right] y[n] e^{-j \omega n} \\
& =\frac{1}{2 \pi} \int X(\theta)\left[\sum y[n] e^{-j(\omega-\theta) n}\right] \mathrm{d} \theta \\
& =\frac{1}{2 \pi} \int X(\theta) Y(\omega-\theta) \mathrm{d} \theta
\end{aligned}
$$

Hence: a product in time becomes a convolution in frequency domain

$$
x[n] y[n] \quad \Leftrightarrow \quad(X * Y)(\omega):=\frac{1}{2 \pi} \int_{-\pi}^{\pi} X(\theta) Y(\omega-\theta) \mathrm{d} \theta
$$

- Special case (modulation):
$y[n]=x[n] e^{j \omega_{0} n} \quad \Leftrightarrow \quad Y(\omega)=X\left(\omega-\omega_{0}\right)$ because $e^{j \omega_{0} n} \Leftrightarrow 2 \pi \delta\left(\omega-\omega_{0}\right)$.

## Exercise [trial exam 2016]

Determine the DTFT $X(\omega)$ of

$$
x[n]=(-1)^{n} u[n]
$$

## Exercise [trial exam 2016]

Determine the DTFT $X(\omega)$ of

$$
x[n]=(-1)^{n} u[n]
$$

For $y[n]=u[n]$ we have seen that $Y(\omega)=\frac{1}{1-e^{-j \omega}}+\pi \sum_{k} \delta(\omega-2 \pi k)$.
We also saw that for a modulation:

$$
(-1)^{n} y[n] \quad \leftrightarrow \quad \frac{1}{2}[Y(\omega-\pi)+Y(\omega+\pi)]=Y(\omega-\pi)
$$

(due to periodicity of the spectrum with period $2 \pi$, both shifts exactly coincide).

Together, we obtain

$$
X(\omega)=\frac{1}{1-e^{-j(\omega-\pi)}}+\pi \sum_{k} \delta(\omega-\pi-2 \pi k)=\frac{1}{1+e^{-j \omega}}+\pi \sum_{k} \delta(\omega-\pi-2 \pi k
$$

## Real-valued signals

For real-valued signals, $x[n]=x^{*}[n]$. Hence

$$
X^{*}(\omega)=X(-\omega)
$$

and thus

$$
|X(-\omega)|=|X(\omega)|: \quad \text { even in } \omega ; \quad \phi(-\omega)=-\phi(\omega): \quad \text { odd in } \omega
$$

It suffices to consider the spectrum on the interval $0 \leq \omega \leq \pi$.

## Even real-valued signals

If moreover $x[n]=x[-n]$, then $X(\omega)$ is real-valued:

$$
X^{*}(\omega)=\sum_{n=-\infty}^{\infty} x^{*}[n] e^{j \omega n}=\sum_{n=-\infty}^{\infty} x[-n] e^{j \omega n}=X(\omega)
$$

The phase spectrum $\phi(\omega)$ is 0 except for jumps of $\pi$ due to sign changes in $X(\omega)$.

## Summary of properties (cf Table 11.1 p.663)

\[

\]

## EE2S31 preview: Discrete Fourier Transform (DFT)

Suppose $x[n]$ has a finite length of $N$ samples (support $0 \leq n \leq N-1$ ), or $x[n]$ is periodic with period $N$, and we consider only 1 period.
The DTFT $X(\omega)$ is a continuous function of $\omega$, with $-\pi \leq \omega<\pi$.
We sample $X(\omega)$ with $N$ samples:

$$
X[k]:=X\left(\omega_{k}\right) \quad \text { with } \quad \omega_{k}=\frac{2 \pi}{N} k, \quad k=0, \cdots, N-1 .
$$

We obtain

$$
X[k]=\sum_{n=0}^{N-1} x[n] e^{-j \frac{2 \pi}{N} k n}
$$

$X[k]$ is called the Discrete Fourier Transform (DFT).

## EE2S31 preview: Discrete Fourier Transform (DFT)

- $N$ samples in frequency suffice to recover $x[n], 0 \leq n \leq N-1$ (outside this interval: periodic or zero)
- Computationally efficient due to the Fast Fourier Transform (FFT)

The DFT en its properties are discussed in EE2S31 (Q4), and in the practical of EE2T11 (Q3).

## Relations

## Generally:

- periodic $\Leftrightarrow$ discrete
- short $\Leftrightarrow$ long
- product $\Leftrightarrow$ convolution
