7.9 Using the loss function

$$
\alpha(\Omega)=10 \log _{10}\left(1+\left[\frac{\Omega}{\Omega_{h p}}\right]^{2 N}\right) \Rightarrow \Omega_{h p}=\frac{\Omega}{\left(10^{0.1 \alpha(\Omega)}-1\right)^{1 / 2 N}}
$$

which gives for $\Omega=2000$

$$
\Omega_{h p}=\frac{2000}{\left(10^{1.94}-1\right)^{0.1}}=1280.9 \mathrm{rad} / \mathrm{sec}
$$

When $\alpha\left(\Omega_{p}\right)=\alpha_{\max }$ we have

$$
\Omega_{p}=\Omega_{h p}\left(10^{0.1 \alpha_{\max }}-1\right)^{1 / 2 N}
$$

which gives after replacing the values on the right term $\Omega_{p}=999.82(\mathrm{rad} / \mathrm{sec})$.
7.11 The following script is used in finding the answers in this problem.

```
% Pr 7_11
clear all; clf
alphamax=0.5 ;alphamin=30; Wp=1500; Ws=3500;
% Butterworth
D=(10^(0.1*alphamin)-1)/(10^(0.1*alphamax)-1);
E=Ws/Wp;
N=ceil(log10(D)/(2*log10(E)))
%Whp=Wp/(10^(0.1*alphamax)-1)^(1/(2*N))
Whp=Ws/(10^(0.1*alphamin)-1)^(1/(2*N))
alpha_p=10*log10 (1+(Wp/Whp)^ (2*N))
alpha_s=10*log10 (1+(Ws/Whp)^ (2*N))
% Chebyshev
N=ceil(acosh(D^(0.5))/acosh(E))
eps=sqrt(10^(0.1*alphamax) - 1)
Whp1=Wp*\operatorname{cosh}(\operatorname{acosh (1/eps)/N)}
alpha_p= 10*log10(1+(eps^2)*(cos(N*acos(1)))^2)
alpha_s=10*log10(1+(eps^2)*\operatorname{cosh}(N*acosh(Ws/Wp))^^2)
%% Check with MATLAB
[N1,Whp1]=buttord(Wp,Ws,alphamax,alphamin,' s')
[N2,Wn]=cheb1ord (Wp,Ws,alphamax,alphamin,'s')
```

The orders and the half-power frequency (Butterworth) and the passband frequency (Chebyshev) are verified using MATLAB functions buttord and cheblord.
(a) The lowpass Butterworth filter that satisfies the specifications is of minimum order $N_{b}=6$, while the corresponding Chebyshev filter has minimum order $N_{c}=4$. Typically for the same specifications $N_{c}<N_{b}$
(b) The half-power frequency of the designed Butterworth filter is $\Omega_{h p}=1787.4$ (calculated so that the $\left.\operatorname{loss} \alpha\left(\Omega_{p}\right)=\alpha_{\max }\right)$. Another possible value for which $\alpha\left(\Omega_{s}\right)=\alpha_{\min }$ is $\Omega_{h p}=1968.4$.
To compute the half-power frequency of the Chebyshev filter we need the ripple factor $\epsilon$ which we find to be 0.3493. We obtain $\Omega_{h p}=1639.7$.
(c) For the designed Butterworth filter with the first value of $\Omega_{h p}$ we get

$$
\begin{aligned}
& \alpha\left(\Omega_{p}\right)=0.5 \mathrm{~dB} \\
& \alpha\left(\Omega_{s}\right)=35.023 \mathrm{~dB}
\end{aligned}
$$

and for the second half-power frequency

$$
\begin{aligned}
& \alpha\left(\Omega_{p}\right)=0.1635 \mathrm{~dB} \\
& \alpha\left(\Omega_{s}\right)=30 \mathrm{~dB}
\end{aligned}
$$

The values of the loss function for the Chebyshev filter are

$$
\begin{aligned}
& \alpha\left(\Omega_{p}\right)=0.5 \mathrm{~dB} \\
& \alpha\left(\Omega_{s}\right)=36.65 \mathrm{~dB}
\end{aligned}
$$

These values do not depend on the half-power frequency but rather on $\Omega_{p}$ which is the normalized frequency.
(d) The formulas for the order of the Butterworth and the Chebyshev filters depend on the ratio of $\Omega_{p}$ and $\Omega_{s}$, so the orders of the filters do not change.

7.12 Since the dc loss is not zero, the normalized loss specifications are

$$
\begin{aligned}
& \alpha_{\max }=\alpha_{1}-\alpha(0)=0.5 \\
& \alpha_{\min }=\alpha_{2}-\alpha(0)=30
\end{aligned}
$$

with a dc loss of 20 dB . The following script is used to find the answers

```
% Pr 7_12
clear all; clf
alphamax=0.5 ; alphamin=30; Wp=1500; Ws=3500;
alpha0=20;
% Butterworth
K=10^(alpha0/20)
D=(10^(0.1*alphamin)-1)/(10^(0.1*alphamax) - 1);
E=Ws/Wp;
N=ceil(log10 (D)/(2*log10 (E)))
Whp=Wp/(10^(0.1*alphamax)-1)^(1/(2*N))
alpha_p=10*log10(1+(Wp/Whp)^ (2*N))
alpha_s=10*log10(1+(Ws/Whp)^(2*N))
% Chebyshev
N=ceil(acosh(D^ (0.5))/acosh(E))
eps=sqrt(10^(0.1*alphamax) -1)
Whp1=Wp*\operatorname{cosh}(\operatorname{acosh}(1/eps)/N)
alpha_p= 10*log10(1+(eps^2)*(cos(N*acos(1)))^2)
alpha_s=10*log10(1+(eps^2)*\operatorname{cosh}(N*\operatorname{acosh}(Ws/Wp) )^2)
alpha1=alpha0+10*log10(1+(eps^2)*cosh(N*acosh(0) )^2);
Kc=10^(alpha1/20)
```

The following are the results

```
% Butterworth
K = 10 % dc gain
N =6 % minimum order
Whp =1.7874e+03 % half-power frequency
alpha_p = 0.5000 % loss at Wp
alpha_s =35.0228 % loss at Ws
% Chebyshev
N = 4 % min order
eps = 0.3493 % ripple factor
Whp1 = 1.6397e+03 % half-power frq
alpha_p = 0.5000 % loss at Wp
alpha_s = 36.6472 % loss at Ws
Kc =10.5925 % dc gain
```

Notice the computation of the dc gain in the Chebyshev filter. In this case the dc loss depends on the order of the filter and so it is not necessarily 0 dB , so to get the dc gain $K_{c}$ we use

$$
\alpha(0)=10 \log _{10}\left[\frac{K^{2}}{1+\epsilon^{2} C_{N}^{2}(0)}\right]=20 \log _{10} K-10 \log _{10}\left(1+\epsilon^{2} C_{N}^{2}(0)\right)
$$

as indicated in the script.
(d) The minimum orders of the filters depend on the ratio of the two frequencies and since it remains the same these do not change.
